

AGENDA

What we'll cover in 10 minutes.

- | | |
|----|---|
| 01 | The Opportunity |
| 02 | The Funnel Discovery |
| 03 | The Two Critical Problems |
| 04 | Solution Space and Strategic Choice |
| 05 | Solution 1 — Selfie Recovery |
| 06 | When Customers Activate |
| 07 | Solution 2 — First-Use Activation Coach |
| 08 | Timing — Lower Profile Sequence |
| 09 | Experiment, Metrics and Guardrails |
| 10 | Expected Impact and Closing |
| 11 | Next Steps |

Onboarding isn't finished when the account is created.

The real goal is first use — the moment a customer actually experiences the product.

THE CHALLENGE

Frente C · Onboarding, funnel abandonment and activation. Use AI to predict drop-off or inactivity and personalize the next step in the onboarding funnel.

NORTH STAR

activated_30d

Share of sign-ups making a first transaction within 30 days.

BASELINE

44.3% Onboarding completion

19.2% Activation within 30 days

260,000 sign-ups, 1.9M events

Seven stages. One clear place we lose people.

44.3%
onboarding completion

19.2%
activated within 30 days

CURRENT SEQUENCE — 260,000 SIGN-UPS

PROPOSED CHANGE ON THE FUNNEL

Moving selfie/liveness earlier means the update nudge (Solution 1) resolves the version issue before the customer's biggest friction point. Since some customers capture their ID photo with the same camera flow, the update may also indirectly improve ID document completion downstream — a secondary effect to validate, not assume.

Two different customers are stuck at two different moments.

PROBLEM 1 — ONBOARDING FRICTION

Selfie / liveness is the largest onboarding bottleneck.

34.2%

of customers abandon at this stage

45%

of all onboarding abandonment happens here

Android on a legacy app version (pre-4.2.0) fails **49.8%** of the time, versus **26%** for every other device/version combination — a 24pp gap driven by a single build.

PROBLEM 2 — ACTIVATION GAP

Completing onboarding isn't enough.

65,168

customers complete onboarding but never transact

56.6%

of completers, within 30 days

The account is ready, but the product hasn't helped the customer reach first value.

04 SOLUTION SPACE AND STRATEGIC CHOICE

Five alternatives, weighed on impact, cost and speed.

ALTERNATIVE	TARGET SEGMENT	IMPACT	COST	SPEED	DECISION
1. Version-aware update nudge	Android, legacy version	High	Low	Fast	Selected — MVP
2. Adaptive selfie capture coach	Retry / liveness-failure signals	High	Med.	Med.	P1 / extension
3. Assisted-verification fallback	2-3 failed attempts	Med.	High	Slow	Future / pilot
4. First-Use Activation Coach	Completed onboarding, not activated	High	Low	Med.	Selected — MVP
5. Acquisition-channel mix shift	Acquisition strategy, new prospects	Med.-long term	High	Slow	Strategic follow-up

WHY FIX THE FUNNEL, NOT THE CHANNEL MIX

The selfie fix benefits every channel at once — including paid social, the worst-performing channel (8.7% activation) and the largest source of volume (34% of sign-ups). Changing channel mix needs CAC, LTV and quality data we don't have yet, and it doesn't repair the product experience itself.

A recovery nudge triggered by the first failed selfie attempt.

- 1 Phone verification
- 2 Personal data
- 3 Selfie / liveness — first attempt

IF ANDROID + LEGACY VERSION AND IT FAILS

Attempt fails → Update prompt shown → Customer updates app →
Back to selfie → Success, continues

- 4 ID document upload
- 5 Address
- 6 Terms acceptance
- 7 Account created

WHY THIS SOLUTION

Deterministic eligibility (device + app version). No identity, fraud or credit decision. Fast, cheap, clear control group.

1 - Phone verification 2 - Personal data 3 - Selfie 4 - Document 5 - Address 6 - Terms 7 - Done

9:41

Step 2 of 7 - Personal data

Your personal details

ELIGIBILITY POLICY (DETERMINISTIC)

Device profile Android · app v3.8.2 {legacy}

Trigger After first failed liveness attempt

Holdout group Preserved

iOS shows no version gap (+2.8pp, within noise) — no prompt is shown there. Android legacy vs. current shows +23.8pp, so only Android legacy is eligible.

EVENT LOG

No events yet — tap Continue on the phone to start.

06 WHEN CUSTOMERS ACTIVATE

Almost everything happens in the first week.

SHARE OF EVENTUAL ACTIVATIONS, BY WEEK

The peak isn't day 0 (6.6%) but days 2 and 3, at 11% each — median time to first transaction is day 5. Nobody transacts instantly; they take a couple of days, then the curve drops off fast.

70.9%

activated by day 7

93.3%

activated by day 14

99.6%

activated by day 28

INTERVENTION WINDOW: DAY 3–10

Before day 3, most customers still activate on their own. After day 10, almost nobody does — this is the window where the Activation Coach can change the outcome.

DAY 14: DEAD-ACCOUNT THRESHOLD

Only 8.4% of activations happen after day 14 — a reasonable cutoff to call an account inactive. The 30-day North Star window isn't cutting anything real: 99.6% of activations happen before day 28.

Three profiles from the activation-propensity model, one action each.

UPPER · $P \geq 0.500$

28%

58.4% actually activate · 1.36× average · 67% referral

No contact

They activate on their own. Held out entirely — the do-no-harm guardrail.

MIDDLE · 0.369–0.500

39%

43.1% activate · 1.01× average · 55% organic

Reminder push

Persuadable, no incentive cost — the MVP's primary target.

LOWER · $P < 0.369$

33%

29.5% activate · 0.69× average · 63% paid social

Push + promotion

Targeting this third reaches 37.5% of everyone who fails to activate.

MIDDLE · DAY 3 Reminder push

One touch only. No incentive.

LOWER · DAY 3 Push 1 — reminder

Same message, no cost. Sent first.

LOWER · DAY 7 Push 2 — promotion

Only if no transaction after push 1.

Three notifications across two profiles.

→ The **Middle profile receives one reminder.**

→ The **Lower profile receives the same reminder first**, then a promotional push a few days later if no transaction has happened.

→ The **Upper profile is deliberately not contacted.**

Read the profiles as a ranking, not a verdict — they track closely with acquisition channel (paid social 63% → 6% → 0%, referral 0% → 7% → 67%).

[See the full prototypes in detail →](#)

Both pushes sit inside the window that still changes the outcome.

Median time to first transaction is day 5, and the peak is days 2–3. Before day 3 most customers still activate on their own; after day 10 almost nobody does.

GUARDRAILS

- Upper profile receives no contact and no incentive.
- A ~20% control arm is held out evenly across all three profiles, so the push effect stays readable within each one.
- Part of the Lower profile runs push-only, so the offer effect can be separated from the push effect.
- Propensity is not uplift. Assigning the incentive to the Lower profile is a hypothesis to be tested, not a finding.

Two solutions, two ways of measuring impact.

MVP 1 — SELFIE RECOVERY

Full rollout, pre/post measurement

A deterministic technical fix — rolled out to all Android + legacy-version customers, no holdout. Measured by comparing selfie/liveness completion in that segment before vs. after launch, using iOS and current-version customers as a natural control (unaffected by the fix).

Primary metric: selfie/liveness completion, Android + legacy segment — *from 50.2% today toward the 74% pass rate seen in the rest of the funnel (+24pp)*

44.3%

baseline onboarding completion

19.2%

baseline activation in 30 days

MVP 2 — ACTIVATION COACH

Randomized A/B test

A discretionary, probabilistic intervention — tested with a real control group before wider rollout, so we know the lift is caused by the Coach and not by who happened to complete onboarding.

Control No intervention

Treatment Activation Coach message

Randomized among medium + low-propensity completers, fired within the day 3–10 window. High-propensity customers are excluded — held out entirely, never contacted.

North Star: $\text{activated_30d} = \text{first transaction within 30 days} \div \text{total sign-ups}$

GUARDRAILS

Cost per incremental activated customer, kept within threshold · high-propensity customers protected by a full holdout, with frequency caps against over-contact.

Two fixes for one funnel: remove friction before activation, convert uncertainty after it.

19.2% → **~22.8%**

Combined North Star effect: **+3.6pp activation within 30 days** (+3.1 to +3.7pp) — roughly 9,400 additional activated customers on a 260,000 sign-up cohort.

MVP 1 · VALIDATED

15,694

additional selfie completions — Android + legacy version recovering to the 26% baseline failure rate

MVP 1 · NORTH STAR

+2.14 to +2.75pp

6,816 incremental activations at the 43.4% midpoint conversion of rescued customers

MVP 2 · HYPOTHESIS

~2,600

additional activations, +1.0pp — 5% relative recovery across the 52,400 non-activated Middle and Lower profile customers

MVP 1 figures come from validated funnel analysis. MVP 2 is a hypothesis sized on the model's own profile base and confirmed only by the A/B test — propensity is not uplift, and the Upper profile stays untouched either way.

What we build next, and what we still need to know.

BUILD

- Pre-start screen listing what's needed (camera, ID) so people don't begin without the means to finish
- Save-and-resume checkpoint before selfie and document upload — the funnel's worst drop-off
- Investigate card delivery time: we have no data on it, and it may be eating the 30-day window
- Test later push timing — push at day 7, promotion at day 14 — so we don't spend on customers who activate on their own
- Longer term: shift acquisition mix away from paid social — highest ceiling, highest cost

DATA

- Cost per push and per checkpoint build
- Size the promotion: MSI vs discount vs cashback, and what each buys
- Run the A/B with control across all three profiles to measure real uplift
